

Building Software with AI

A short overview of how I build software with modern AI tools.

"The typing is not the job.
The judgment is."

How I Build Software

I use AI as an engineering collaborator, not an autopilot.

Before writing code, I spend most of my time understanding the problem, breaking it into smaller pieces, deciding what should be built first, and verifying every implementation before it becomes part of the product.

A Typical Feature

Example Requirement

Allow senior citizens using ChillGui to access emergency contacts from any screen in two taps or fewer.

My First Notes

Instead of immediately asking AI to write code, I first answer a few questions myself.

- What is the actual user problem?
- What should happen if permissions are denied?
- Does this belong in the accessibility layer or the launcher?
- Can this feature work without changing existing applications?
- What is the simplest solution that satisfies the requirement?

Representative AI Prompt

Read the requirement below.
Do not write code yet.
Break the feature into independently implementable tasks.
Identify possible edge cases.
Explain any assumptions.
Return only the engineering plan.
Don't hallucinate.

My Review

When AI returns a solution, I usually ask questions like:

- Is this actually solving the user's problem?
- Is the architecture unnecessarily complicated?
- Can another engineer understand this quickly?
- Are important edge cases missing?
- Would I merge this into production today?

Engineering Principle

I try to use AI to reduce repetitive work, not to outsource engineering judgment.

Case Study — ChillGui

The Problem

Modern mobile applications are often designed for experienced users. Many senior citizens struggle with complex interfaces, inconsistent layouts, small touch targets and multi step work-flows that make everyday tasks unnecessarily difficult.

Instead of asking every application developer to redesign their product, I wanted to build an accessibility layer that could simplify existing applications while preserving their original functionality.

Project Snapshot

Project	ChillGui
Category	Accessibility • On-device AI
Status	Indian Patent Application No. 202611055813
Recognition	Overall Winner Aurora Global Hackathon 2026

Product Screenshot

Key Engineering Decisions

Decision		Reasoning
Accessibility	Mid- dleware	Preserves compatibility with existing Android applications instead of replacing them.
On-device	Pro- cessing	Reduces unnecessary data transmission and improves responsiveness.
Simple	Interaction Model	Reduced the number of user actions required for common tasks.
Modular	Compo- nents	Made individual features easier to improve and test independently.

Where AI Added Value

- Exploring implementation alternatives.
- Refactoring repetitive code.
- Speeding up debugging.
- Improving documentation.
- Generating implementation drafts for review.

Where I Took Ownership

- Product vision.
- System architecture.
- Accessibility decisions.
- Integration.
- Testing.
- Final implementation decisions.

Decision Log

This page illustrates how I typically reason through product and engineering decisions before implementation. The goal is not to maximise the amount of AI-generated code, but to arrive at the simplest reliable solution.

Example Feature

Objective

Allow senior users to quickly access emergency contacts from anywhere inside the interface.

Requirements

- Reach emergency contacts in two interactions or fewer.
- Avoid interfering with the underlying application.
- Keep the interaction consistent across different apps.
- Preserve accessibility and readability.

Options Considered

Approach	Decision
Floating Action Button	Rejected. Could obscure important UI elements and behave inconsistently across applications.
Gesture Shortcut	Rejected. Hidden gestures are difficult to discover and remember, especially for the target users.
Dedicated Accessibility Shortcut	Selected. Predictable, simple, and compatible with the existing interaction model.

How AI Helped

- Suggested multiple implementation approaches.
- Compared tradeoffs between alternatives.

- Generated implementation drafts.
- Helped identify possible edge cases.

My Responsibility

- Choosing the final design.
- Validating assumptions.
- Integrating the feature.
- Testing behaviour.
- Deciding what ultimately ships.

Key Observation

The difficult part was not generating implementation ideas.

The difficult part was selecting the approach that best balanced simplicity, usability, maintainability, and long term reliability.

If We Worked Together

Throughout this brief, I've tried to show how I think rather than simply listing technologies I've used.

The tools will continue to evolve.

Good engineering judgement remains valuable regardless of the model, framework or programming language.

What You Can Expect

- I begin by understanding the problem before proposing solutions.
- I use AI to accelerate implementation while remaining responsible for correctness.
- I break larger features into smaller, independently reviewable tasks.
- I question assumptions before integrating generated code.
- I value readable, maintainable software over clever solutions.
- I take ownership of what reaches production.

The best engineering workflow is not the one that generates the most code.

It is the one that consistently ships reliable software.

Why This Role

One sentence from your job description stood out immediately:

"The typing is not the job.
The judgment is."

That sentence is the reason I decided to prepare this brief.

It reflects how I already think about modern software engineering: AI can dramatically accelerate development, but responsibility for the product always remains with the engineer.

Thank you for your time.
